Setting up the *Second Security Password* for the first time

Second Security Password is a type of "second password" to log into the system, in that way that adds to the system even more security attribute by enable the Two-factor authentication and it's required in that format that the user must enter the 3 (three) values or 3 (three) digit pin depending on each position of characters from the *Second Security Password* set up.

To be able to login to the iTms the first required fields are *Username* and *Password*.

After entering these credentials, if the current user does not have the *Second Security Password* configured, he/she must set a new one, as shown on the picture below.

After this process, the system will request from the user to enter again only the *Second Security Password* 3 digit pin as confirmation of Two-factor authentication that everything is set up correctly, and it's read to go.

Example:
If the *Second Security Password* given in the process above is "**abcdefghijk**" and the system from the user requires the characters in these positions **2,3,5** then the user must enter "**bce**".
